

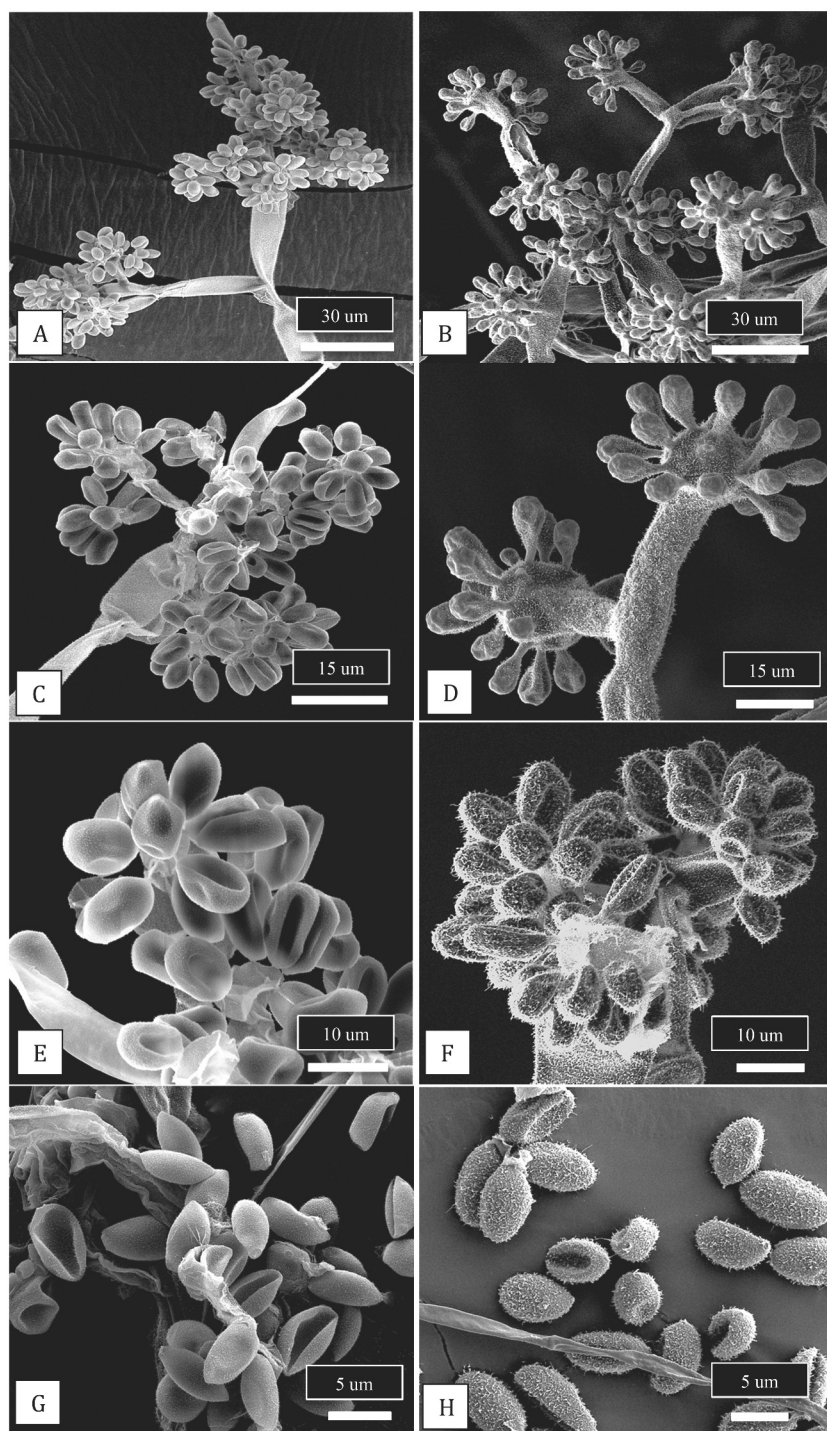

Fig. 4 Scanning electron micrographs of conidiophores and conidia of two *Botrytis* species originating from cannabis plants. Conidiophores of *B. cinerea* (a, c) and *B. porri* (b, d) showing differences in branching pattern. Comparison of conidial morphology of *B. cinerea* (e, g) and *B. porri* (f, h). *Botrytis cinerea* has a smooth surface and smaller conidial size compared to *B. porri*. All images were taken from 2-week-old cultures of both species grown on PDA under identical conditions.

buds pre-treated with *G. catenulatum* showed significantly reduced development of mycelium of *Botrytis* compared to the control (Fig. 11d). Visually, the

Gliocladium-treated buds showed a white surface growth developing after 10 days (Fig. 11e), which when streaked out on PDA or following dilution plating gave
