

Fig. 7 The impact of *Hop latent viroid* infection on development of trichomes on inflorescence leaves and bracts. a) genotype 'chocolate fondue' shows a silvery appearance on the inflorescence leaves and bracts (arrow) on a healthy plant (left) reflecting the normal development of trichome glands compared to an HLVD-infected plant (right) in which trichome development is considerably reduced. (b) same as (a) but on genotype 'Headband' in which trichome development on the bracts of a healthy inflorescence (left) is much greater than on an infected inflorescence (right). (c) magnified view of an inflorescence bract of genotype 'Mac-1' under a dissecting microscope (50 $\times$) showing the healthy trichomes with long stalks and fully developed trichome heads (left) compared to the much reduced trichome stalks and smaller heads on a bract from an HLVD-infected plant (right).
