

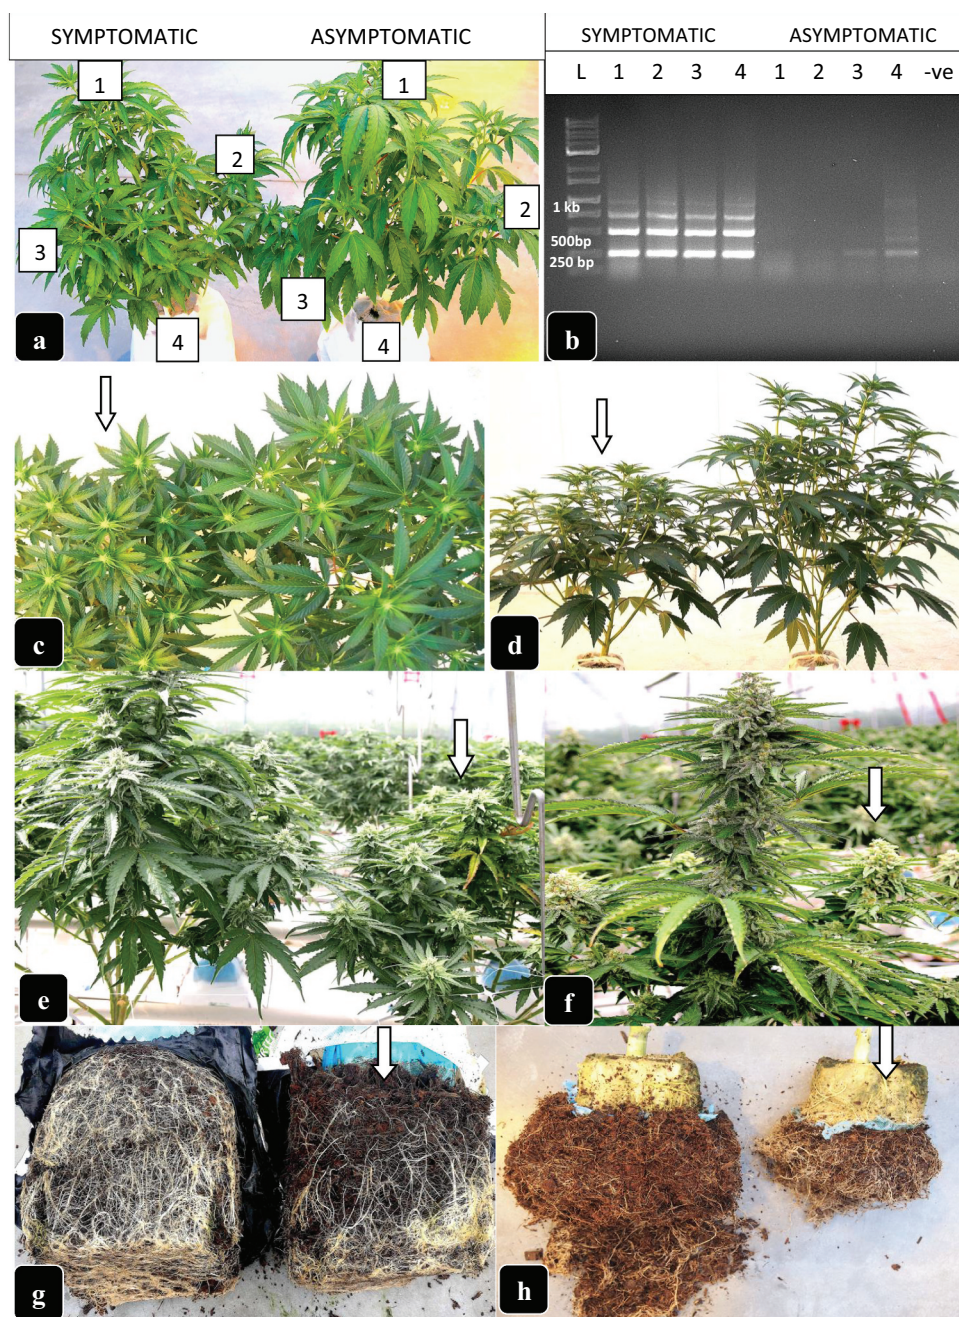

**Fig. 3** Symptoms due to *Hop latent viroid* infection on flowering plants of cannabis. (a) comparison of symptomatic plant (left) with asymptomatic plant (right) after two weeks into the flowering period. Leaf samples were collected for analysis at the positions indicated by (1–4). (b) RT-PCR gel showing bands characteristic of HLVD present in the symptomatic plants shown in (a). The asymptomatic plant showed very faint bands only in the roots. (c–f) comparison of symptomatic plants (arrows) with asymptomatic plants at 3–4 weeks into flower development (c, d) and at 7–8 weeks (e, f) of development. (g, h) reduction in root volume and root mass as a result of HLVD infection in cannabis genotypes ‘Powdered Donuts’ (g) and genotype ‘Mac-1’ (h). Arrows in all photos show the infected plants.
